# Introduction to Haskell

Functional programming in Haskell

Ivan Trepakov

NSU Sys.Pro

#### **Functional**

- Functions as first-class citizens
- Higher order functions
- Declarative style

#### **Functional**

- Functions as first-class citizens
- Higher order functions
- Declarative style

#### Pure

- Side-effect separation
- Equational reasoning
- Simplified parallelism

#### **Functional**

- Functions as first-class citizens
- Higher order functions
- Declarative style

#### Pure

- Side-effect separation
- Equational reasoning
- Simplified parallelism

#### Lazy

- Infinite data structures
- Compositional programming style
- Tricky to evaluate complexity

#### **Functional**

- Functions as first-class citizens
- Higher order functions
- Declarative style

#### Pure

- Side-effect separation
- Equational reasoning
- Simplified parallelism

#### Lazy

- Infinite data structures
- Compositional programming style
- Tricky to evaluate complexity

## Statically typed

- "If a program compiles, it probably works"
- Expressive type system
- Type inference

# Installing Haskell toolchain

#### Official installer GHCup

- GHC (Glasgow Haskell Compiler)
- GHCi interactive REPL-like environment
- HLS (Haskell Language Server) integration with editors
- cabal and stack tools for package management and development

\$ ghc --version
The Glorious Glasgow Haskell Compilation System,
version 9.4.8

Note: any version above 9.x.x will be fine

https://www.haskell.org/ghcup/

#### **GHC** interactive

## Using GHCi

- :? help
- :quit or :q quit
- :load or :l load module
- :reload or :r reload modules
- :info or :i information about identifier
- :type or :t type of expression
- :set / :unset set or unset options

```
$ ahci
GHCi, version 9.4.8:
https://www.haskell.org/ghc/ :? for help
ghci> 2
ahci> True
True
ghci> 'a'
'a'
ahci> "Hello"
"Hello"
ahci> [1.2.3]
[1.2.3]
ghci> (12, True)
(12, True)
ahic> :a
Leaving GHCi.
```

# Evaluating expressions

#### Arithmetic

ahci> 2 + 3

```
qhci> 2 + 3 * 2
ahci> (-2) * 4
- 8
ghci> 5.0 / 2.0
2.5
ahci> 5 `div` 2
ghci> 5 `mod` 2
```

## Booleans and comparisons

```
ahci> True && False
False
ghci> True || False
True
ahci> not True
False
ahci> 5 == 2 + 3
True
ahci > 5 /= 2 + 3
False
ghci> True > False
True
```

## Operators are functions

```
ahci> (+) 2 3
ghci> div 5 2
ghci> max 5 2
ghci> 5 `max` 2
```

# Associativity and precedence

#### Symbolic operators

- Any non-alphanumeric identifier is considered operator and *infix* by default
- But can be made *prefix* by enclosing in parentheses
- Associativity and precedence must be explicitly specified

#### Alphanumeric functions

- Any alphanumeric identifier is prefix by default
- But can be made *infix* by enclosing in backticks
- Function application has highest precedence and always left-associative

```
ahci > 2 + (3 * 2)
ghci> :i (+)
type Num :: * -> Constraint
class Num a where
  (+) :: a -> a -> a
    -- Defined in `GHC.Num'
infixl 6 +
ahci> :i (*)
type Num :: * -> Constraint
class Num a where
  (*) :: a -> a -> a
    -- Defined in `GHC.Num'
infixl 7 *
```

# Associativity and precedence

#### Symbolic operators

- Any non-alphanumeric identifier is considered operator and *infix* by default
- But can be made prefix by enclosing in parentheses
- Associativity and precedence must be explicitly specified

## Alphanumeric functions

- Any alphanumeric identifier is *prefix* by default
- But can be made *infix* by enclosing in backticks
- Function application has highest precedence and always left-associative

```
ghci> max 2 3 + 2
4
ghci> (max 2 3) + 2
4
ghci> max 2 (3 + 2)
5
ghci> min 4 (max 2 3)
3
```

## Anatomy of declaration

Here is sample Haskell declaration:

## Anatomy of declaration

Here is sample Haskell declaration:

```
x :: Int -- Type declaration
x = 42 -- Value declaration
```

name = expression is a binding (not assignment)

- :: reads as "has type"
- = reads as "defined to be"

Multiple declarations with the same name are not allowed!

Compiler will let us know about it with error:

```
Multiple declarations of 'x'
```

#### Anatomy of declaration

Here is sample Haskell declaration:

```
x :: Int -- Type declaration
x = 42 -- Value declaration
```

name = expression is a binding (not assignment)

- :: reads as "has type"
- = reads as "defined to be"

Multiple declarations with the same name are not allowed!

Compiler will let us know about it with error:

```
Multiple declarations of 'x'
```

What does this declaration mean? And what is its type if any?

$$y = y + 1$$

#### Anatomy of declaration

Here is sample Haskell declaration:

```
x :: Int -- Type declaration
x = 42 -- Value declaration
```

name = expression is a binding (not assignment)

- :: reads as "has type"
- = reads as "defined to be"

Multiple declarations with the same name are not allowed!

Compiler will let us know about it with error:

```
Multiple declarations of 'x'
```

What does this declaration mean? And what is its type if any?

```
-- Fixed-precision integer
i :: Int
i = 12
Guaranteed<sup>1</sup> to be at least [-2^{29}, 2^{29} - 1], but
usually is machine word sized
-- Actual bounds
minInt. maxInt :: Int
minInt = minBound
maxInt = maxBound
```

<sup>&</sup>lt;sup>1</sup>See Haskell 2010 Language Report, Section 6.4 Numbers

```
-- Fixed-precision integer
                                               -- Arbitrary-precision integer
i :: Int
                                               n :: Integer
i = 12
                                               n = 2 ^ (2 ^ (2 ^ (2 ^ 2)))
Guaranteed<sup>1</sup> to be at least [-2^{29}, 2^{29} - 1], but
                                               numDigits :: Int
usually is machine word sized
                                               numDigits = length (show n)
-- Actual bounds
minInt. maxInt :: Int
                                               -- >>> numDigits
minTnt = minBound
                                               -- 19729
maxInt = maxBound
```
